Security and privacy

Data at rest

- Pault stores prompts locally using SwiftData in the app's sandboxed container.
- The app does not implement its own encryption at rest. Use macOS full-disk encryption (FileVault) and device management policies if encryption is required.

Data in transit

- The current app target performs no network requests and contains no telemetry or analytics code.
- Prompt data stays on-device unless a user copies it to the clipboard.

Clipboard and paste behavior

- Copy actions write prompt content to the macOS clipboard (NSPasteboard).
- Paste actions in the launcher simulate Cmd+V to the frontmost app. Clipboard contents can be read by other apps while present in the pasteboard.

Permissions and system prompts

- Global hotkey registration uses the Carbon event manager.
- Simulated paste uses CGEvent via AccessibilityHelper and requires macOS Accessibility permission. The app automatically prompts for permission on the first paste attempt using `AXIsProcessTrustedWithOptions`.

Logging

- The app uses Apple's unified logging framework (`os.Logger`) for error and informational messages (e.g., hotkey registration failures, accessibility permission status, preference changes).
- Logs are written to the system log and can be viewed in Console.app. There is no remote log shipping in the current app target.
